Usually, the screws are either screw holes on the interface of the electronic products, or holes on the printed circuit board (PCB). In some designs, the screw holes on the interface or PCB are formed by laser drilling or laser punching. However, for an in-depth hole, a high-power laser and powerful processing tools are required. For the purpose of increasing the reliability of the electronic product, screws with small size are usually adopted. However, the screw holes of the conventional electronic products are formed by the conventional high-power drilling, which may easily cause damage to the product. The conventional design can only be used for the plastic products, and the existing design cannot be directly used for the glass products. Besides, the screw holes with large diameter are limited in the glass products, thus affecting the application of electronic products. To overcome the above-mentioned problems, those skilled in the art make great efforts.1. Field of the Invention The present invention relates to electrical power conversion, and, in particular, to electrical power conversion systems and methods of operation thereof. 2. Description of the Related Art Conventional electric motors are typically operated in either a forward or reverse direction. Power is applied to the motor in either direction and, if necessary, the motor is switched in the opposite direction. As such, it would be beneficial to have an electric motor that has the ability to both operate in a forward and reverse direction so that power can be applied to the motor in either direction. The power required to operate the motor is typically provided by a power source such as an alternating current (AC) 82157476af
